Summary

The spanwise distribution of bound circulation on a semi-span wing and the flow velocities in its wake were measured in a wind tunnel. Particular attention was given to documenting the flow velocities in and around the developing tip vortex. A two-component laser velocimeter was used to make the velocity measurements. This report presents, without discussion, the spanwise distribution of bound circulation, three components of the time-averaged velocities throughout the near wake and their standard deviations, and the integrated forces and moments on a metric tip as measured by an internal strain gage balance.

INTRODUCTION

An experimental investigation documenting the spanwise distribution of bound circulation and the flow velocities in the wake of a semi-span wing has been conducted in the 7- by 10-Foot Wind Tunnel at Ames Research Center. A two-component laser doppler velocimeter was used to make the measurements. The bound circulation at each spanwise location on the wing was obtained by measuring the velocities tangent to a rectangular path enclosing the wing section (see references 1-3 for more details of the procedure). While investigating the characteristics of the wing wake, particular attention was given to measuring the flow velocities in and around the developing tip vortex.

This experiment was the first in a series of experiments designed to investigate the wake and loading characteristics of a hovering helicopter rotor. The next experiment in the series will document the spanwise loading and wake velocities of a model-scale hovering helicopter rotor. The twist distribution of the wing was designed such that the spanwise variation of bound circulation would nominally match that of the hovering model rotor blade. The helicopter rotor will be operated at full-scale tip speeds and at a tip Reynolds number that matches that of the semi-span wing. The details of the structure of the tip vortex and the spanwise variation of bound circulation in the two tests will be compared. The objective is to determine if a non-rotating wing can be used as an analogue to a hovering helicopter rotor for rotor wake and loading investigations. There are several advantages to testing a semi-span wing instead of a helicopter rotor if it can be demonstrated that the data obtained from the semi-span wing can be used to

improve our understanding of phenomenon associated with a hovering helicopter rotor. For example, it is more convenient to build and test large chord semi-span wings than rotor blades. As a consequence of the semi-span wing's larger size, finer details of the tip vortex structure can be resolved. Also, it is much easier to make measurements near a wing whose position is fixed than it is to make measurements near a rotor blade operating at a tip speed of over 200 m/s.

This report presents, without discussion or analysis, the data obtained in this test. Presented, in tables and plots, are the spanwise distribution of bound circulation, three components of the time-averaged velocities throughout the near wake and their standard deviations, and the integrated forces and moments on the metric tip of the wing as measured by an internal strain gage balance.

EXPERIMENTAL EQUIPMENT AND PROCEDURES

Description of Model

The semi-span wing had a rectangular planform with a span of 1.524 m and a chord of 0.209 m. A portion of the wing, extending from the tip to 0.432 m (2.07 chords) inboard of the tip, was mounted on an internal six-component strain gage balance to measure the forces and moments on the wing tip. The wing was mounted both horizontally and vertically in the wind tunnel during the test because the laser velocimeter was only capable of measuring streamwise and vertical velocity components. Therefore, in order to measure the spanwise component of velocity, it was necessary to also test the wing in the vertical position. The wing angle of attack in the vertical position was

adjusted to yield the same lift coefficient as the horizontal position, as measured by the internal strain gage balance. Figure 1 presents a photograph of the wing installed in the wind tunnel in the horizontal position. The view is looking downstream at the wing. Figure 2 presents a photograph of the wing installed in the vertical position, once again looking downstream. The tip of the wing was at the centerline of the wind tunnel for both the horizontal and vertical installations. Figure 3 presents an installation drawing showing a plan view of the wing installed in the horizontal position. Figure 4 is a drawing of the wing installed in the horizontal position, looking downstream. Figure 5 presents a view of the wing installed in the wind tunnel in the vertical position, once again looking downstream. A splitter plate was used when the wing was installed in the horizontal position so that 1.066 m (5.1 chords) of the wing extended into the wind in both the vertical and horizontal installations.

The wing had a square tip, as if the wing had been sawed off (see fig. 1). The wing airfoil section was a V23010-1.58 with a 0° deflection trailing edge tab. The trailing edge tab was 4% of the chord and the airfoil thickness to chord ratio was 10.2%. The airfoil coordinates are given in table I. The wing was twisted nonlinearly from root to tip. Figure 6 presents the wing's angle of attack distribution across the span. The angle of attack was measured from the airfoil reference line ($Z = 0$ of table I). The angle of attack was not varied during this test.

Description of Balance

The balance used to measure the forces and moments on the metric tip of the wing was a 6-component internal strain gage balance (Task Corp. MK XXIX-B). Figure 3 shows the location of the balance and the balance moment center. The balance moment center was at the wing quarter-chord, halfway between the upper and lower surfaces of the wing, and 0.386 m inboard of the tip of the wing.

Instrumentation, Data Acquisition and Reduction

A laser velocimeter (LV) was used to nonintrusively measure the flow velocities in the wind tunnel. The LV system was of the dual-beam backscatter type and could simultaneously measure two components of the flow velocity (streamwise and vertical). The LV was the same instrument used in the investigations of references 4-6, and the reader is referred to these papers for a detailed description of the LV.

Data from the LV, the wing tip-mounted strain gage balance, and the wind tunnel dynamic pressure transducer were acquired by a minicomputer-based data acquisition system and stored on a floppy disk. The use of the minicomputer enabled the experimenter to evaluate the data being acquired on-line and repeat data points as required. The data acquisition system was the same one used in the investigations of refs. 4 and 6, and the reader is referred to these papers for a complete description of the system.

At each point in the flow-field where the velocity was measured, 100 samples of LV velocity data were acquired. From these 100 samples a mean and standard deviation were computed. The wing local section lift coefficient was computed by the circulation box technique (refs. 1-3). Briefly,

the circulation box technique is based on Stoke's Theorem, which states that the total vorticity inside a closed contour is equal to the line integral of the tangential velocity around the contour. Thus, by measuring the tangential flow velocities on the sides of a rectangular contour (box) surrounding a wing section, the bound circulation at that section and, therefore, the lift coefficient can be calculated.

The velocity was measured at 26 points on each side of the circulation box. Figure 7 presents a sketch of the circulation box around a wing section, showing the points where the velocity was measured and the coordinates of the corners of the box.

Figure 8 presents a sketch of the coordinate system used in this test. The origin is at the intersection of the airfoil reference system z axis with the leading edge of the airfoil. The x axis is parallel to the free stream, the z axis is vertical, and the y axis is parallel to the wing quarter-chord line. It should be noted that this coordinate system was defined relative to the tip of the wing with the wind off. At the nominal test dynamic pressure of 2100 N/m^2 , the tip of the wing deflected up 0.009 m (0.043 chords) due to the lift load on the wing. No corrections to the data in this report have been made to account for this deflection.

TEST CONDITIONS

The test was conducted at a dynamic pressure of $2100 \text{ N/m}^2 \pm 3\%$ and at atmospheric stannation pressure. The angle of attack was set to 6.57° at the metric break (2.07 chords inboard of the tip). The Reynolds number based on chord was $845,000$ and the Mach number was 0.17 .

RESULTS

The spanwise variation of section lift loading is presented in figure 9. Tabulated values are presented in table 2. Tabulated data from the internal strain gage balance are presented in table 3. The data are presented in non-dimensional coefficient form.

$$C_L = \text{Lift}/q A_{\text{tip}}$$

$$C_D = \text{Drag}/q A_{\text{tip}}$$

$$C_M = \text{Pitching Moment}/q A_{\text{tip}}c$$

$$C = \text{Rolling Moment}/q A_{\text{tip}}c$$

$$C_N = \text{Yawing Moment}/q A_{\text{tip}}c$$

where c = the wing chord

$$q = \text{measured dynamic pressure, } 1/2 \rho U_{\infty}^2; \text{ and}$$

$$A_{\text{tip}} = \text{the planform area of the wing tip}$$

For each run, the means and standard deviations of the forces and moments are presented. At least 10 samples of balance data were taken during each run. Note that this data represents forces and moments on the metric tip, and not of the entire wing.

Wake Velocity Data

An extensive survey of the flow velocities in the wing wake is presented in tabular form in appendix A. As previously noted, each point of velocity data is the mean of 100 samples, and the standard deviation associated with the mean is also presented. The data in appendix A are organized by the streamwise location of the sub-plane, X/C , and then by sub-planes, "A" through "G".

All of the velocity data in appendix A have been non-dimensionalized by the free-stream velocity, U_∞ . Data were acquired at 4 streamwise locations in the wing wake: 1.02, 1.8, 2.6, and 3.5 chords downstream of the wing leading edge. At each streamwise location at least 7 "sub-planes" of data were acquired. The sub-planes were nominally centered on the wing tip trailing vortex and were "nested" such that each succeeding sub-plane provides finer spatial resolution than the one preceding it. The sub-planes were labeled "A" through "G" with the "A" plane being the largest. Figure 10 presents a sketch of the wake velocity survey sub-planes showing their relative sizes and locations. An "A" plane is also shown on figs. 4 and 5 illustrating the relative position of the plane. Figure 3 shows the streamwise location of the wake velocity survey planes relative to the wing. Table 4 presents the nominal coordinates of the edges of the sub-planes.

When the wing was mounted in the horizontal position, the streamwise velocity, U , and the vertical velocity, W , were measured. When the wing was mounted in the vertical position, the streamwise velocity, U , and the spanwise velocity, V , were measured. Thus, to obtain all three components of the flow velocity the data from the horizontal and vertical installations must be combined. This has been done for the data presented in appendix A. For those sub-planes where the velocities were measured both in the horizontal and vertical installations, all of the velocity data is presented. $U(H)$ denotes the streamwise velocity measured in the horizontal installation and $U(V)$ denotes the streamwise velocity measured in vertical installation. Some sub-planes of velocity data were acquired for only one wing position, and this data lacks one component of the velocity. Note that several repeat runs were made for some sub-planes.

A limited amount of data were acquired in an attempt to use the LV to measure the wing section profile drag from wake velocity defect measurements. These data are presented as "W", for "wake", sub-planes. In order to evaluate the repeatability of the velocity data, data were taken at the same location 5 times. These data are presented as "R", for "repeatability" sub-planes.

CONCLUDING REMARKS

Nonintrusive measurements of the flow velocities in the near wake and the developing tip vortex of a semi-span wing have been made. Additionally, the spanwise distribution of the bound circulation has been documented. These data should be useful for validating any theory that calculates the development of the tip vortex.

5. Abstract → The spanwise distribution of bound circulation on a semi-span wing and the flow velocities in its wake were measured in a wind tunnel. Particular attention was given to documenting the flow velocities in and around the developing tip vortex. A two-component laser velocimeter was used to make the velocity measurements. This report presents, without discussion, the spanwise distribution of bound circulation, three components of the time-averaged velocities throughout the near wake and their standard deviations, and the integrated forces and moments on a metric tip as measured by an internal strain gage balance. ←
